Chickpea (*Cicer arietinum*) is the second most widely grown legume crop after soybean, accounting for a substantial proportion of human dietary nitrogen intake and playing a crucial role in food security in developing countries. We report the ~738-Mb draft whole genome shotgun sequence of CDC Frontier, a *kabuli* chickpea variety, which contains an estimated 28,269 genes. Resequencing and analysis of 90 cultivated and wild genotypes from ten countries identifies targets of both breeding-associated genetic sweeps and breeding-associated balancing selection. Candidate genes for disease resistance and agronomic traits are highlighted, including traits that distinguish the two main market classes of cultivated chickpea—*desi* and *kabuli*. These data comprise a resource for chickpea improvement through molecular breeding and provide insights into both genome diversity and domestication.

# Kabuli chickpea reference

# Kabuli chickpea reference

# Desi chickpea reference

# How do we validate and fix a reference genome

# Skim GBS

- Determine SNPs by sequencing parents and running SGSautoSNP
- Low coverage skim sequence segregating population
- Map reads to the reference genome
- Call genotype where reads cover previously defined SNP
- Impute and clean to define haplotype blocks

# Genotype calling

Call genotype of previously predicted SNPs

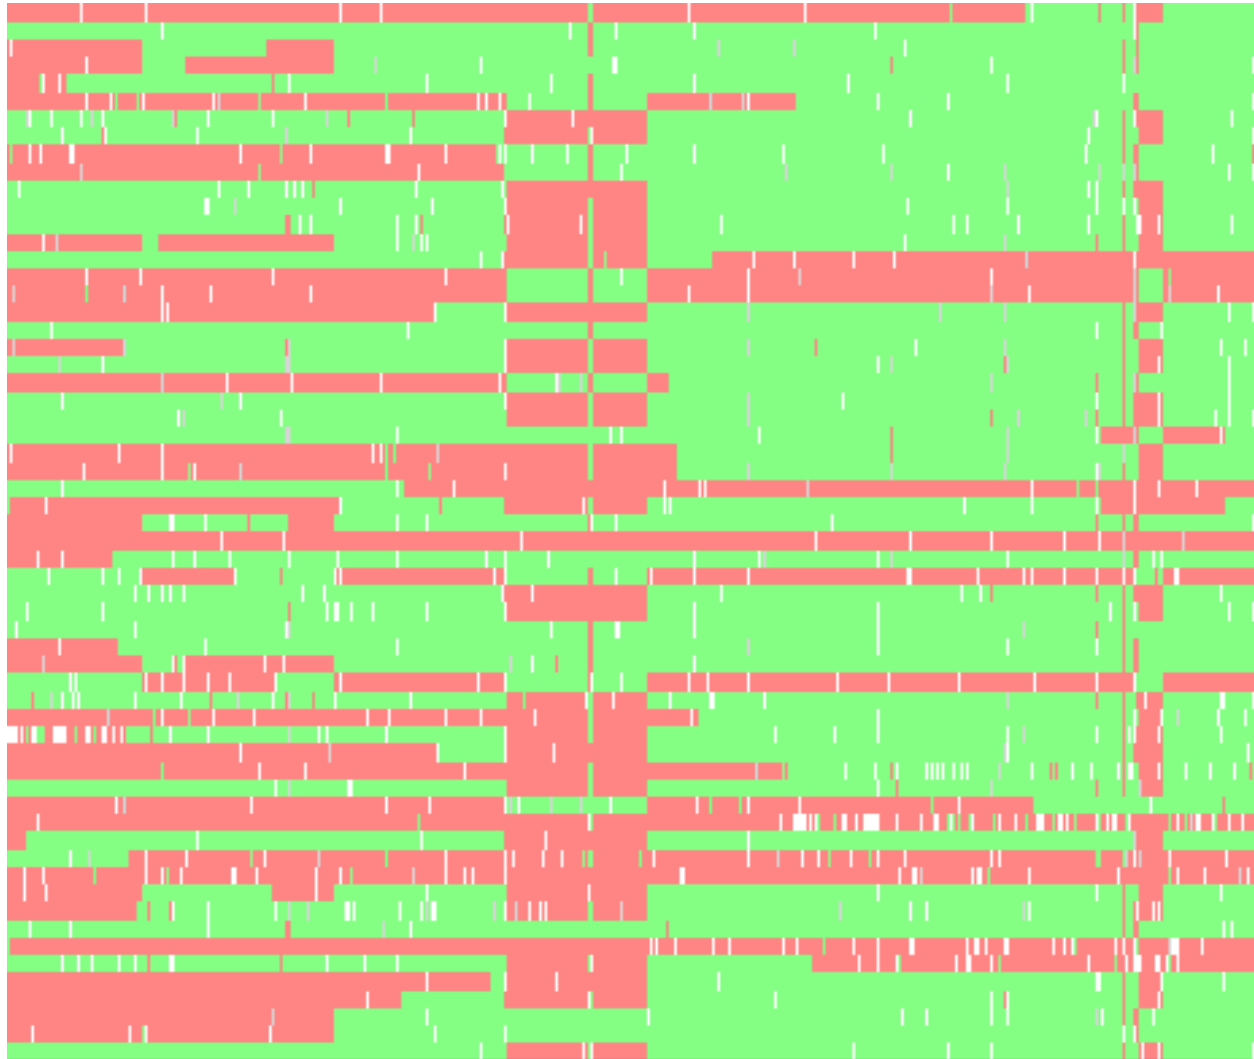

# Haplotype blocks

# Pre imputation

# After imputation and cleaning

# Genotyping by sequencing

- 92 double haploid Tapidor x Ningyou individuals
- Called SNPs for parents, assigned parental genotypes to all alleles in the population
- Used these alleles to
  - create genetic maps
  - place unplaced contigs
  - identify misplaced and chimeric contigs

# GBS applications

- Check for misplaced contigs based on recombination events shared between individuals

- Red: Tapidor, green: Ningyou, dark red: heterozygous allele, white: missing

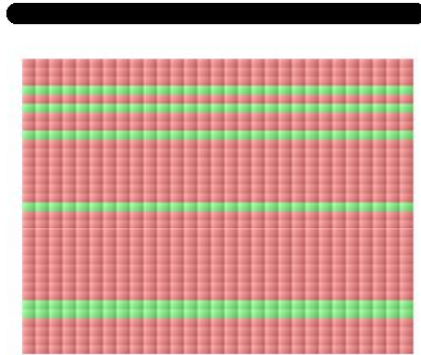

# Placing unplaced contigs: contigPlacer

- Compare unplaced contigs with all placed contigs
- Use metaSNPs
- Penalized Hamming distance to compare alleles between two SNPs
- Places unplaced contig next to the best possible placed contig
- Possible to reverse contig if latter half of contig fits better to best partner than first half

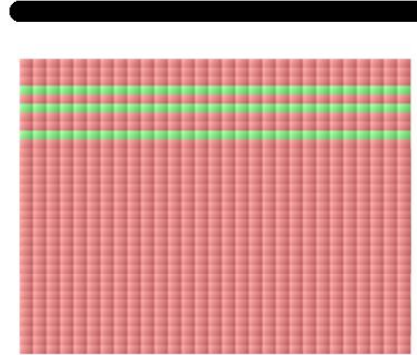

# contigPlacer 1

# Placing contigs in Darmor

- Total size: 850 Mbp
- Was 645 Mbp placed in pseudomolecules
- Now 800 Mbp placed in pseudomolecules,
- 50 Mbp unplaced (contigs with no SNPs or chimeric)
- Genes on pseudomolecules from 63,904 to 75,955
- Only 3,528 genes remain unplaced
